Early Local Correlation Approaches

The idea of local correlation is almost as old as correlation theory itself and has been suggested long before even Hartree-Fock calculation on medium sized molecules were feasible

O Sinanoglu *Adv. Chem. Phys.*, **1964**, 6, 315

RK Nesbet, *Adv. Chem. Phys.*, **1965**, 9, 321

it took almost 20 years before it was taken up again. An important paper is from Cullen and Zerner (received no attention, perhaps because it was in a semi-empirical context)

JM Cullen, MC Zerner *J. Chem. Phys.*, **1982**, 77, 4088

Followed by the pioneering work of Pulay and Saebo (CISD, MP4)

P Pulay, *Chem. Phys. Lett.* **1983**, 100, 151.; S Saebo, P Pulay, *Chem. Phys. Lett.* **1985**, 113 13.

P Pulay, S Saebø, *Theor. Chim. Acta* **1986** 69, 357.; S Saebo, P Pulay, *J. Chem. Phys.* **1987**, 87 914.

And the early coupled cluster work (mostly CCD)

RJ Bartlett, GD Purvis, *Int. J. Quantum Chem.* 14, 561 **1978** WD Laidig, GD Purvis III, RJ Bartlett, *Int. J. Quantum Chem., Symp.* 16, 561 **1982**. WD Laidig, GD Purvis III RJ Bartlett, *Chem. Phys. Lett.* 97, 209

1983; WD Laidig, GD Purvis III RJ Bartlett, *J. Phys. Chem.* 89, 2161 **1985**; W Förner, J Ladik, P Otto, J Čížek, *Chem. Phys.* 97, 251 **1985** W Förner, *Chem. Phys.* 114, 21 **1987** M Takahashi J Paldus, *Phys. Rev. B* 31, 5121 **1985**

... given the hard- and software limitation at the time real applications were not feasible

Local Correlation: Importance of Accuracy Goals

The idea of local correlation methods is:

- ✓ preserve - *as much as possible* - the accuracy of wave function based correlation approaches.
- ✓ Reduce the unfavorable scaling with system size - *ideally to linear*

HOWEVER

- ➔ **One will only get wave function based ab initio quality, if the error that we introduce by exploiting the locality is not spoiling the intrinsic accuracy of the method!**
- ➔ Example: In a large molecule the correlation energy is **$\sim 10 E_h = 6270$ kcal/mol**
- ➔ Chemical accuracy is ~ 1 kcal/mol
- ➔ **The target accuracy MUST be 99.9 to 99.99% of E_c to preserve the features of the methods**
- ➔ **Error cancellation in local approximations is NOT better than about 1 order of magnitude**

Principles of Local Correlation Theory

Pretty much all local correlation methods:

$$E_{corr} = \sum_{\text{Chunks } K=1}^{N_K} \delta E_K \approx \sum_{\text{Chunks } K'=1}^{N'_K < N_K} \delta E_K^{(approx)}$$

Approximation 1

Approximation 2

where „chunks“ =

Fragments, Atoms, Atom Pairs, Orbitals, Orbital Pairs, ..

Decomposition of the Exact Correlation Energy

Start from the Schrödinger equation $\hat{H}_{BO} \Psi = E \Psi$

Insert the full CI expansion

$$\hat{H}_{BO} (\Phi_{HF} + \sum_{ia} C_a^i \Phi_i^a + (\frac{1}{2!})^2 \sum_{ijab} C_{ab}^{ij} \Phi_{ij}^{ab} + \dots) = E (C_0 \Phi_{HF} + \sum_{ia} C_a^i \Phi_i^a + (\frac{1}{2!})^2 \sum_{ijab} C_{ab}^{ij} \Phi_{ij}^{ab} + \dots)$$

Multiply with the HF function from the left:

$$\underbrace{\langle \Phi_{HF} | \hat{H}_{BO} | \Phi_{HF} \rangle}_{E_{HF}} + \sum_{ia} C_a^i \underbrace{\langle \Phi_{HF} | \hat{H}_{BO} | \Phi_i^a \rangle}_{F_{ia} = 0 \text{ (Brillouin)}} + \frac{1}{4} \sum_{ijab} C_{ij}^{ab} \underbrace{\langle \Phi_{HF} | \hat{H}_{BO} | \Phi_{ij}^{ab} \rangle}_{\langle ij || ab \rangle}$$

$$= E \left(\underbrace{\langle \Phi_{HF} | \Phi_{HF} \rangle}_1 + \sum_{ia} C_a^i \underbrace{\langle \Phi_{HF} | \Phi_i^a \rangle}_0 + \frac{1}{4} \sum_{ijab} C_{ij}^{ab} \underbrace{\langle \Phi_{HF} | \Phi_{ij}^{ab} \rangle}_0 \right)$$

Thus:

$$\frac{1}{4} \sum_{ijab} C_{ab}^{ij} \langle ij || ab \rangle = \frac{1}{2} \sum_{ij} \varepsilon_{ij} = E_{corr} \quad \text{(Nesbet's theorem)}$$

If we know the precise values of the double excitation coefficients we know the EXACT correlation energy! It is a sum of **PAIR CORRELATION ENERGIES**

Approximation 1: Locality of Pair Correlation Energies

Multipole Based Pair Prescreening

✓ **MP2** pair correlation energy: $\epsilon_{ij}^{SC-MP2} = - \sum_{ab} \frac{4(ia | jb)(ia | jb) - 2(ia | jb)(ib | ja)}{\epsilon_a + \epsilon_b - F_{ii} - F_{jj}}$

„Coulomb“ „Exchange“ → 0

✓ **Long Range Multipole Approximation**

$$\epsilon_{ij}^{DIP} = - \frac{4}{R_{ij}^6} \sum_{\tilde{\mu}_i \tilde{\nu}_j} \frac{\left\{ \langle i | \mathbf{r} | \tilde{a}_i \rangle \langle j | \mathbf{r} | \tilde{b}_j \rangle - 3 \left(\langle i | \mathbf{r} | \tilde{a}_i \rangle \mathbf{R}_{ij} \right) \left(\langle j | \mathbf{r} | \tilde{b}_j \rangle \mathbf{R}_{ij} \right) \right\}^2}{\epsilon_{\tilde{a}_i} + \epsilon_{\tilde{b}_j} - F_{ii} - F_{jj}}$$

- ▶ Drop pairs below a (conservative) selection threshold → linear scaling (ij)
- ▶ Correction for dropped pairs

$$\Delta E_{Pre} = \sum_{ij(dropped)} \epsilon_{ij}^{DIP}$$

(this is actually very small relative to the residual error of the method)

Chemically Speaking: How Local is the Correlation?

| | | | | |
|------------|---|----------------|----------|-------|
| ΔE | = | $+1.9 \pm 0.5$ | kcal/mol | Exp. |
| | | -11.4 | kcal/mol | HF |
| | | -0.4 | kcal/mol | CCSD |
| | | -8.4 | kcal/mol | B3LYP |
| | | -9.9 | kcal/mol | BLYP |

Semi-Local Correlation Effects

➡ We really need to capture both: semi-local and dispersion effects

➡ Correlation is not quite as local as we'd like it to be!

Approximation 2: Local Excitation Spaces

- ✓ The **occupied (internal) orbitals** localize nicely (mostly, that is)

➔ *Significant MO coefficients extend over only a few atoms (1-5)*

- ✓ Pair correlation energies based on localized internal orbitals show locality with the expected R^{-6} decay

- ✓ The **virtual (external) orbitals** are problematic

- ➔ *„Chaotic“, delocalized nature*
- ➔ *„Building higher and higher towers with smaller and smaller stones*
- ➔ *Truncation schemes based on canonical MOs are unlikely to be highly successful*

Local Excitation Spaces

Let us go back to our analysis of the leading correlation term

$$\varepsilon_{ij}^{SC-MP2} \approx -4 \sum_{ab} \frac{(ia | jb)^2}{\varepsilon_a + \varepsilon_b - F_{ii} - F_{jj}}$$

In order for this term to be significant

orbital a must be close to i AND orbital b must be close to j

in mathematical terms

The orbital pair ia and jb must have a significant *differential overlap*

Consequence: We can focus on local excitations and neglect long range charge transfer

However: A local representation of the virtual space is necessary

BUT: Standard localization schemes do not work well (but see Jörgensen et al)

- ▶ in particular for large basis sets the virtual orbitals do not localize well since the orthogonality constraint leads to highly oscillatory behavior
- ▶ Most researchers: Choose a non-orthogonal, local representation

Projected Atomic Orbitals

Projected atomic orbitals, PAOs, Pulay, P. *CPL*, 1983, 100, 151

$$|\tilde{\mu}\rangle = (1 - \sum_i |i\rangle\langle i|)|\mu\rangle$$

- ➡ PAO's are local close to the ,parent' atom (but have significant tails)
- ➡ PAO's span the virtual space and are orthogonal to the occupied space
- ➡ PAO's are non-orthogonal and linearly dependent

Orthonormal Localized Virtual Orbitals

IM Hoyvik, K Kristensen, T Kjaergaard, P Jørgensen *Theo. Chem. Acc.*, **2014**, 133, 1417

- ▶ Careful comparison of PAOs and standard localized virtual MOs
- ▶ Suggested localization functional

$$L = \sum_i \left| \left\langle \psi_i \left| (\mathbf{r} - \mathbf{R}_i)^4 \right| \psi_i \right\rangle \right|^2 \quad \mathbf{R}_i = \left\langle \psi_i \left| \mathbf{r} \right| \psi_i \right\rangle$$

Fourth 'central moment'
(emphasizes the LMO tail region) Center of gravity of MO i

Diamond (localized)

Graphene (delocalized)

it seems possible to generate orthonormal virtual molecular orbitals that are as good or better than PAOs

Local Correlation Approaches

Methods to exploit the locality of electron correlation fall into two broad categories:

1) „**Piecewise**“ **Local Approaches** (Stoll, Piecuch, Kallay, Li, Jörgensen, Friedrich, ...)

- ✓ *Locality is used by dividing the molecule into subsystems (molecular fragments, orbital groups, ...).*
- ✓ *Small calculations are carried out on one, two, three ... subsystems at the time and*
- ✓ *Results are combined to estimate the total correlation energy*

2) „**Direct**“ **Local Approaches** (Pulay, Werner/Schütz, FN, ...)

- ✓ *Locality is used in the algorithm to avoid the computation of terms that are near zero or factors that are unity.*
- ✓ *Some kind of localized representation of the virtual space is required*

„Piecewise“ Local Correlation Schemes

The Cluster in Molecules (CIM) Approach

The Cluster in Molecules (CIM) approach was proposed by Li et al. and adopted by Piecuch et al. and Kallay et al.

Let us start from the (orbital invariant) coupled cluster energy expression

$$E_C = \sum_{ia} t_a^i f_{ia} + \frac{1}{4} \sum_{ijab} (t_{ab}^{ij} + t_a^i t_b^j) \langle ij || ab \rangle$$

and re-write it in terms of single-occupied orbital increments:

$$E_C = \sum_i \delta E_i \quad \delta E_i = \sum_a t_a^i f_{ia} + \frac{1}{4} \sum_{jab} (t_{ab}^{ij} + t_a^i t_b^j) \langle ij || ab \rangle$$

let the occupied orbital be localized.

Replace: $\psi_i(\mathbf{r}) = \sum_{\mu} c_{\mu i} \mu(\mathbf{r}) \rightarrow \psi_i(\mathbf{r}) \approx \sum_{\mu \in \{i\}} c_{\mu i} \mu(\mathbf{r})$

{i} is the orbital domain of localized MO i and contains the AOs of all atoms to ensure a population of at least 1.98 when summed. Threshold τ Very small: 1-3 atoms!

The Cluster in Molecules (CIM) Approach

Now use the off-diagonal Fock matrix elements $F_{ij} > \zeta_1$ to select orbitals j interacting with i

→ **Environment $[i]=[i, j_{1i}, j_{2i}, \dots, j_{Ni}]$** (Approximation 1)

Associated with the primary environment are the AOs that are the union of the AO domains of the orbitals in the environment

→ **AO domain $[\mu]_i$**

Finally, the virtual space for the domain of orbital i is spanned by the PAO's belonging to the atoms that compose the AO domains

→ **PAO domain $[\tilde{\mu}]_i$** (Approximation 2)

After orthogonalization, removal of linear dependencies and cutting small AO contributions, there is a set of orthonormal virtual orbitals that belong to the domain of i

(the actual algorithms are more involved than this, but the essence is just this)

An Integral-Direct Linear-Scaling Second-Order Møller–Plesset Approach

Good

**Problem:
the largest subsystem
calculation is too large
to be doable with a
regular CCSD(T)
program**

Strengths and Weaknesses of Piecewise Schemes

Advantages

- ✓ Relatively **easy to implement** and intuitively appealing
- ✓ Extensive **reuse of canonical code** or even driving existing canonical programs
- ✓ **Readily extended to properties**
- ✓ **Parallelizes** with extremely high efficiency

Disadvantages

- ✓ **Redundancy**: Need for overlapping fragments leads to redundant integral calculations and amplitude optimizations.
- ✓ **Feasibility**: If the largest subsystem gets too large to be done by a regular correlation program, the method fails (Not a big problem for MP2, but very big problem for CCSD(T) or even higher)
- ✓ **Generality**: Fragmentation may not be straightforward in electronically complicated or heavily delocalized situations (does not apply to CIM and DEC)
- ✓ **Practicality**: Very few chemical applications; no extended benchmarks

Direct Local Correlation Schemes

Local MP2 Theory

Two complications relative to canonical MP2:

- ▶ At first sight the use of **non-orthogonal orbitals** appears to be „nightmare“ of added complexity. However, the PAO's remain orthogonal to the occupied space and there are never more than two PAOs in any excited determinant
- ▶ In the local representation the **Fock matrix is no longer diagonal** and hence the usual Möller Plesset expansion does not apply.

Pulay and Saebø suggested to use the **Hylleraas functional** instead

$$E^{(2)} = \min(2\langle \Psi^{(1)} | H | \Psi^{(0)} \rangle + \langle \Psi^{(1)} | H_0 - E_0 | \Psi^{(1)} \rangle)$$

it readily leads to an orbital invariant formulation of MP2

$$\Psi = \Psi^{(0)} + \Psi^{(1)} = \Psi_{HF} + \frac{1}{4} \sum_{ijab} C_{ab}^{ij} \Phi_{ij}^{ab}$$

$$H = H_0 + V \quad H_0 = F, \quad V = H - H_0$$

Local MP2 Theory

$$\langle \Psi^{(1)} | H | \Psi^{(0)} \rangle = \frac{1}{4} \sum_{ijab} C_{ab}^{ij} \langle ij || ab \rangle$$

$$\langle \Psi^{(1)} | H_0 - E_0 | \Psi^{(1)} \rangle = \frac{1}{8} \sum_{ijabc} C_{ab}^{ij} F_{cb} C_{ac}^{ij} - \frac{1}{8} \sum_{ijkab} C_{ab}^{ij} F_{jk} C_{ab}^{ik}$$

Minimization w.r.t. the coefficients C leads to the linear equation system:

$$R_{ab}^{ij} = \langle ij || ab \rangle + \sum_c (C_{ac}^{ij} F_{cb} + F_{ac} C_{cb}^{ij}) - \sum_k (C_{ab}^{ik} F_{kj} + F_{ik} C_{ab}^{kj}) = 0$$

Which immediately leads back to canonical MP2 if the Fock operator is diagonal.

If now the virtual orbitals are replaced by non-orthogonal PAO's, only a slight complication arises. The first order wave function is:

$$\Psi^{(1)} = \frac{1}{4} \sum_{ij\tilde{\mu}\tilde{\nu}} C_{\tilde{\mu}\tilde{\nu}}^{ij} \Phi_{ij}^{\tilde{\mu}\tilde{\nu}}$$

Local MP2 Theory

The residual becomes:

$$R_{\tilde{\mu}\tilde{\nu}}^{ij} = \langle ij || \tilde{\mu}\tilde{\nu} \rangle + \sum_c (F_{\tilde{\mu}\tilde{\kappa}} C_{\tilde{\kappa}\tilde{\tau}}^{ij} \tilde{S}_{\tilde{\tau}\tilde{\nu}} + \tilde{S}_{\tilde{\mu}\tilde{\kappa}} C_{\tilde{\kappa}\tilde{\tau}}^{ij} F_{\tilde{\tau}\tilde{\nu}}) - \sum_k (F_{ik} \tilde{S}_{\tilde{\mu}\tilde{\kappa}} C_{\tilde{\kappa}\tilde{\tau}}^{kj} \tilde{S}_{\tilde{\tau}\tilde{\nu}} + F_{kj} \tilde{S}_{\tilde{\mu}\tilde{\kappa}} C_{\tilde{\kappa}\tilde{\tau}}^{ik} \tilde{S}_{\tilde{\tau}\tilde{\nu}}) = 0$$

or: $\mathbf{R}^{ij} = \mathbf{K}^{ij} + (\mathbf{F}\mathbf{C}^{ij}\tilde{\mathbf{S}} + \tilde{\mathbf{S}}\mathbf{C}^{ij}\mathbf{F}) - \sum_k (f_{ik}\tilde{\mathbf{S}}\mathbf{C}^{kj}\tilde{\mathbf{S}} + f_{kj}\tilde{\mathbf{S}}\mathbf{C}^{ik}\tilde{\mathbf{S}}) = 0$

With the PAO overlap matrix $\tilde{S}_{\tilde{\mu}\tilde{\nu}} = \langle \tilde{\mu} | \tilde{\nu} \rangle$

So far: **no approximation!**

These equations represent a more complicated and ill-conditioned way to do MP2!

- ▶ Owing to the linear dependencies in the PAO set, the equations are singular.
- ▶ Removing the singularities by diagonalizing of the PAO overlap matrix and dropping the eigenvectors corresponding to zero eigenvalues leads back to canonical MP2

➔ **Introduce correlation domains for each electron pair ij**

PAO's, Domains and Pair Domains

➔ A **domain** $\{\mu\}_i$ is a set of PAOs chosen for a given internal LMO according to some prescription

J. W. Boughton and P. Pulay, *J. Comp. Chem.* 14, 736 **1993**.

➔ A **pair domain** $\{\mu\}_{ij}$ is the union of the individual orbital domains

$$\{\mu\}_{ij} = \{\mu\}_i \cup \{\mu\}_j$$

- ➔ Fine, but for sufficient accuracy (99.9%) domains become impractically large
- ➔ Need „compaction“ of the space

Domain Construction

Our proposal: **Differential Overlap Integral**

$$DOI_{ik} = \sqrt{\int |f_i(\mathbf{r})|^2 |g_k(\mathbf{r})|^2 d\mathbf{r}}$$

PAOs that have a DOI above threshold with the LMO in question are added to the domain (then atom completed)

Actual spatial extent of the virtual space is taken into account

Excellent approximation to the the Schwartz screening integrals

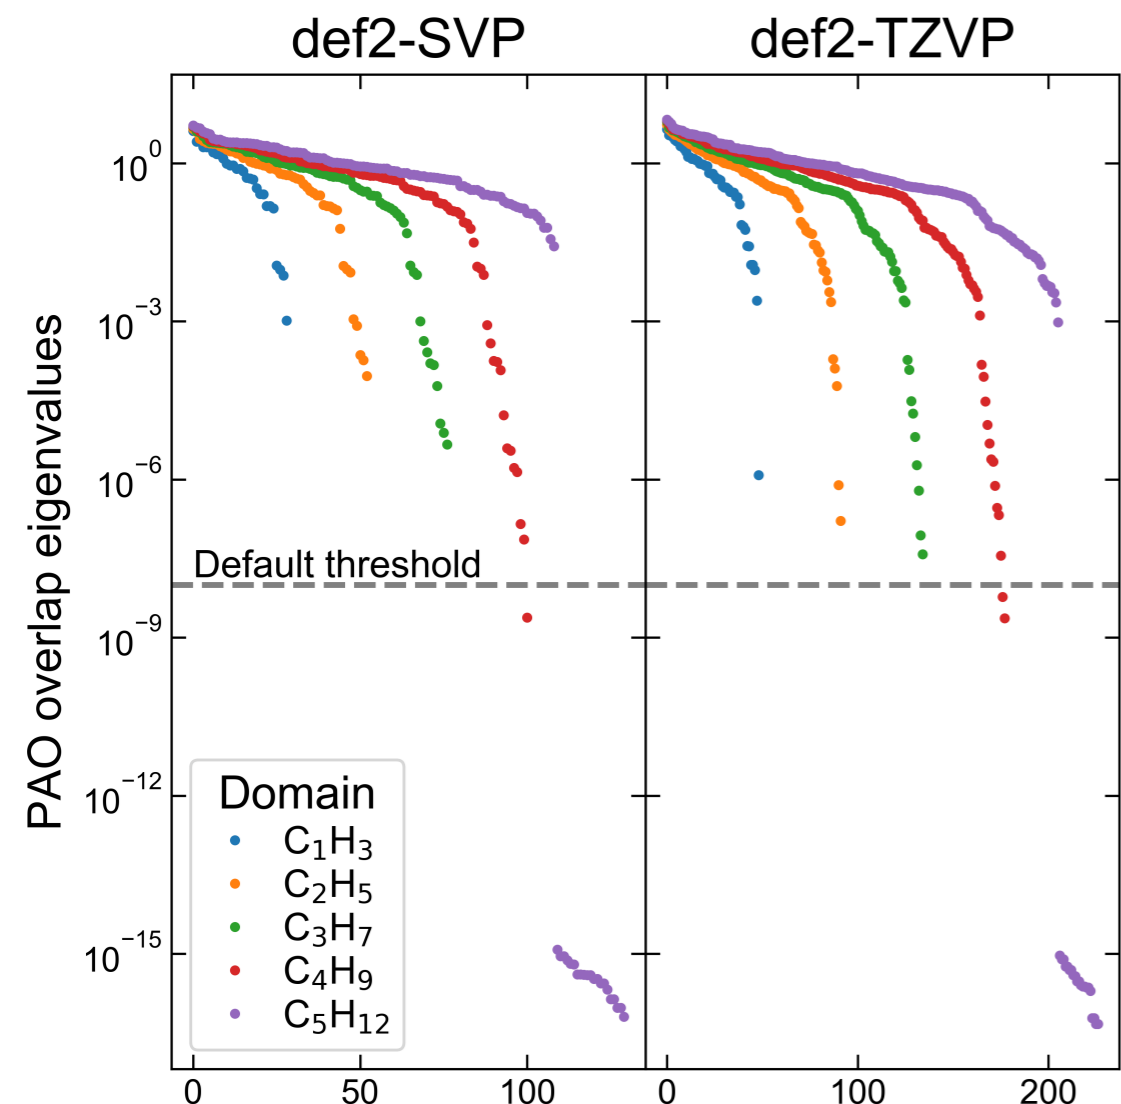

Easy to compute efficiently in linear scaling for any set of functions

Properties of the PAO's in Domains

$$|\tilde{\mu}\rangle = \left(\hat{1} - \sum_i |\mathbf{i}\rangle \langle \mathbf{i}| \right) |\mu\rangle$$

- ▶ Not normalized
- ▶ Guaranteed to be linearly dependent (spans the virtual space only and has full AO dimension)
- ▶ Somewhat local

$$\{\tilde{\mu}_i\}$$

- ▶ Now normalized but still not orthogonal and linearly dependent
- ▶ Diagonalize PAO overlap in a given domain and discard eigenvectors to eigenvalues $< 10^{-8}$ (smallest possible to retain numerical stability)
- ▶ Diagonalize the Fock operator in the non-redundant space to get to normalized, non-redundant, quasi-canonical PAO's

Local MP2 Theory

Using the domains, the residual becomes

$$\mathbf{R}^{ij} = \mathbf{K}^{ij} + (\mathbf{F}^{(ij)} \mathbf{C}^{ij} \tilde{\mathbf{S}}^{(ij,ij)} + \tilde{\mathbf{S}}^{(ij,ij)} \mathbf{C}^{ij} \mathbf{F}^{(ij)}) - \sum_k (f_{ik} \tilde{\mathbf{S}}^{(ij,jk)} \mathbf{C}^{kj} \tilde{\mathbf{S}}^{(kj,ij)} + f_{kj} \tilde{\mathbf{S}}^{(ij,ik)} \mathbf{C}^{ik} \tilde{\mathbf{S}}^{(ik,ij)}) = 0$$

Where all matrices are now local:

$$\left. \begin{array}{l} R_{\tilde{\mu}\tilde{\nu}}^{ij} \rightarrow R_{\tilde{\mu}\in\{ij\},\tilde{\nu}\in\{ij\}}^{ij} \\ K_{\tilde{\mu}\tilde{\nu}}^{ij} \rightarrow K_{\tilde{\mu}\in\{ij\},\tilde{\nu}\in\{ij\}}^{ij} \\ F_{\tilde{\mu}\tilde{\nu}}^{(ij)} \rightarrow F_{\tilde{\mu}\in\{ij\},\tilde{\nu}\in\{ij\}} \\ \tilde{S}_{\tilde{\mu}\tilde{\nu}}^{(ij,kl)} \rightarrow \tilde{S}_{\tilde{\mu}\in\{ij\},\tilde{\nu}\in\{kl\}} \end{array} \right\} \quad \checkmark \text{ Sub-matrices can either be stored or constructed on the fly}$$

Two more steps are necessary to reach linear scaling

1. **Discard weakly interacting electron pairs:**

In almost all local treatments done by *distance criteria* (R_{ij} =distance between orbital centroids)

2. **Discard small terms in the sum over \mathbf{k}** by analyzing f_{ik}, f_{jk}

Threshold $F_{\text{cut}} \sim 10^{-5} E_h$

PAO based Local Correlation Treatments

➔ Discontinuous potential energy surfaces due to small and changing domains along the PES

➔ Reply:

Calculation of smooth potential energy surfaces using local electron correlation methods

Ricardo A. Mata and Hans-Joachim Werner^{a)}

THE JOURNAL OF CHEMICAL PHYSICS **125**, 184110 (2006)

In either PAO based or CIM based procedures the correlation energy recovered depends critically on the PAO domains.

... how large do they have to be in order to lead to an accurate result?

How Large do Domains have to be?

$T_{DO}=0.1$ 98.4% E_{corr} $N_{av_{PAO}}=115$

$T_{DO}=0.01$ 99.7% E_{corr} $N_{av_{PAO}}=588$

$T_{DO}=0.001$ 99.9% E_{corr} $N_{av_{PAO}}=935$

At the domain size one reaches target accuracy the average number of PAOs per domain is too large for the calculation to be efficient or even doable

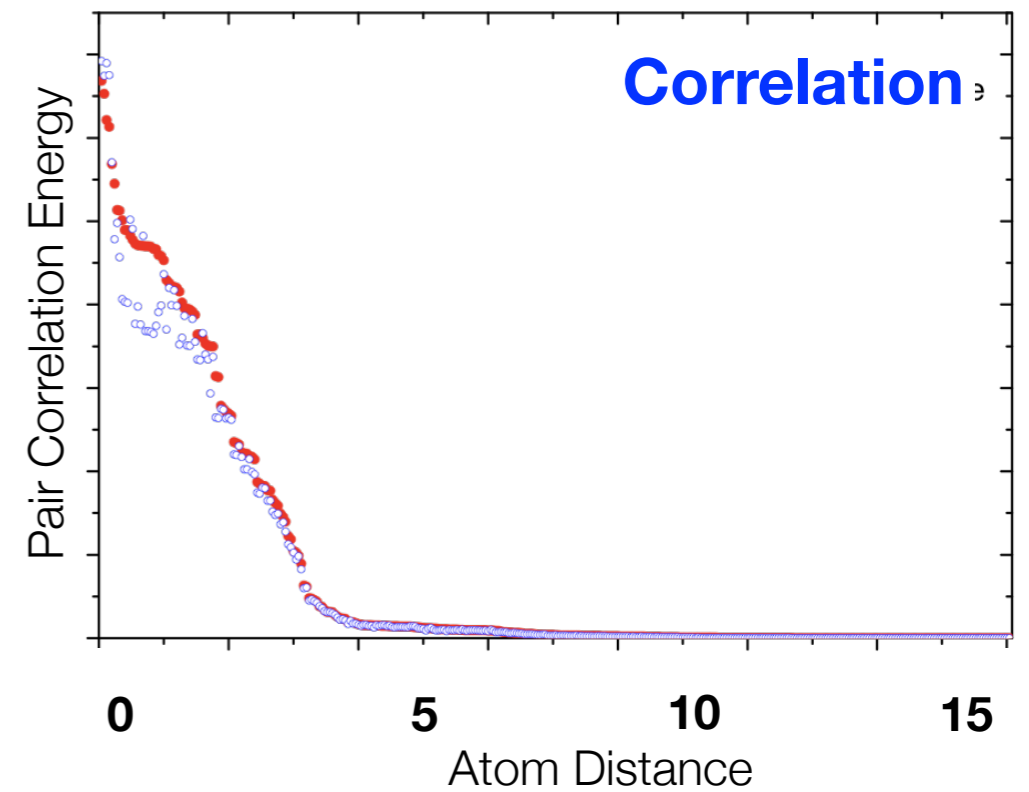

There are important correlation effects that are not *that* local

Natural Orbitals

PHYSICAL REVIEW

VOLUME 97, NUMBER 6

MARCH 15, 1955

Quantum Theory of Many-Particle Systems. I. Physical Interpretations by Means of Density Matrices, Natural Spin-Orbitals, and Convergence Problems in the Method of Configurational Interaction*

PER-OLOV LÖWDIN

*Department of Physics, Massachusetts Institute of Technology, Cambridge, Massachusetts, and
Institute of Mechanics and Mathematical Physics, Uppsala University, Uppsala, Sweden*

(Received July 8, 1954)

in the k -space, i.e., the charge- and bond-order matrix, is *Hermitean*, and it is therefore possible to find a unitary matrix \mathbf{U} which transforms this matrix to diagonal form with the eigenvalues $n_{kk} = n_k$:

$$\mathbf{U}^\dagger \boldsymbol{\gamma} \mathbf{U} = \mathbf{n} = \text{diagonal matrix.} \quad (72)$$

We have further, in matrix form, $\boldsymbol{\gamma} = \mathbf{U} \mathbf{n} \mathbf{U}^\dagger$, and, if we introduce a new set of spin-orbitals χ_k by the matrix relation $\boldsymbol{\chi} = \boldsymbol{\psi} \mathbf{U}$, or

$$\chi_k = \sum_{\alpha} \psi_{\alpha} U_{\alpha k}, \quad (73)$$

we may rewrite the density matrix in the form

$$\gamma(\mathbf{x}_1' | \mathbf{x}_1) = \sum_k n_k \chi_k^*(\mathbf{x}_1') \chi_k(\mathbf{x}_1). \quad (74)$$

This form is characterized by the fact that all bond orders are vanishing, and the new spin-orbitals χ_k will therefore be called the *natural spin-orbitals* associated

4. NATURAL SPIN-ORBITALS AND THE CONVERGENCE PROBLEM IN THE METHOD OF CONFIGURATIONAL INTERACTION

Its convergence properties may now be understood from the relations (63), (64), and (74). In the limiting case, when exactly N natural spin-orbitals are fully occupied and the relation $\boldsymbol{\gamma}^2 = \boldsymbol{\gamma}$ is fulfilled, the natural expansion (80) is reduced to a *single* Slater determinant. In considering the convergence, this is of course the most favorable case. However, if only a finite number of the occupation numbers n_k in (74) are essentially different from zero, the natural expansion (80) will be reduced to a sum of determinants over all ordered configurations associated with these essentially occurring spin-orbitals, i.e., to a sum of comparatively few terms. The introduction of natural spin-orbitals seems therefore to provide a simple solution of the convergence problem, previously discussed by Slater.¹⁷

Note added in proof.—It is desirable to have also a more exact mathematical measure for the rapidity of convergence of the two configurational interaction series (66) and (80). We note that, according to (60) and (63), the charge order $\gamma(k)$ gives the probability for the ordinary spin-orbital ψ_k to occur in the expansion of the total wave function Ψ . If only M of the numbers $\gamma(k)$, $k=1, 2, 3, \dots$, are essentially different from zero, then the number of essential terms in (66) is given by the corresponding number of possible configurations: $M!/N!(M-N)!$. In using this procedure, however, it is necessary to evaluate the individual quantities $\gamma(k)$ and to distinguish between essential and unessential charge orders.

A still simpler measure of convergence may be constructed by observing that the charge orders always lie between 0 and 1 and that, in the limiting cases $\gamma(k)=0$ and $\gamma(k)=1$, the corresponding spin-orbital ψ_k occurs in none or in all of the terms in (66), respectively, without contributing to the slowing down of the convergence of the series. The eventual slowness of the convergence of (66) depends instead on the possibility for an electron to be distributed over two or more spin-orbitals, giving charge orders of an intermediate order of magnitude, $0 < \gamma(k) < 1$. The rapidity of convergence of (66) may therefore be measured by the smallness of the quantity

$$\vartheta = (1/N) \sum_k \{1 - \gamma(k)\} \gamma(k) = 1 - (1/N) \sum_k \{\gamma(k)\}^2,$$

which fulfills the inequality of $0 \leq \vartheta < 1$. In considering different basic sets $\psi_1, \psi_2, \psi_3, \dots$ for the description of the same total wave function Ψ , it is clear that the natural spin-orbitals χ_k are characterized by having the *smallest ϑ value possible*. According to (72), we have $\gamma = \mathbf{U}\mathbf{n}\mathbf{U}^\dagger$ and $\gamma^2 = \mathbf{U}\mathbf{n}^2\mathbf{U}^\dagger$, leading to $\text{Tr}(\gamma^2) = \text{Tr}(\mathbf{n}^2)$ and

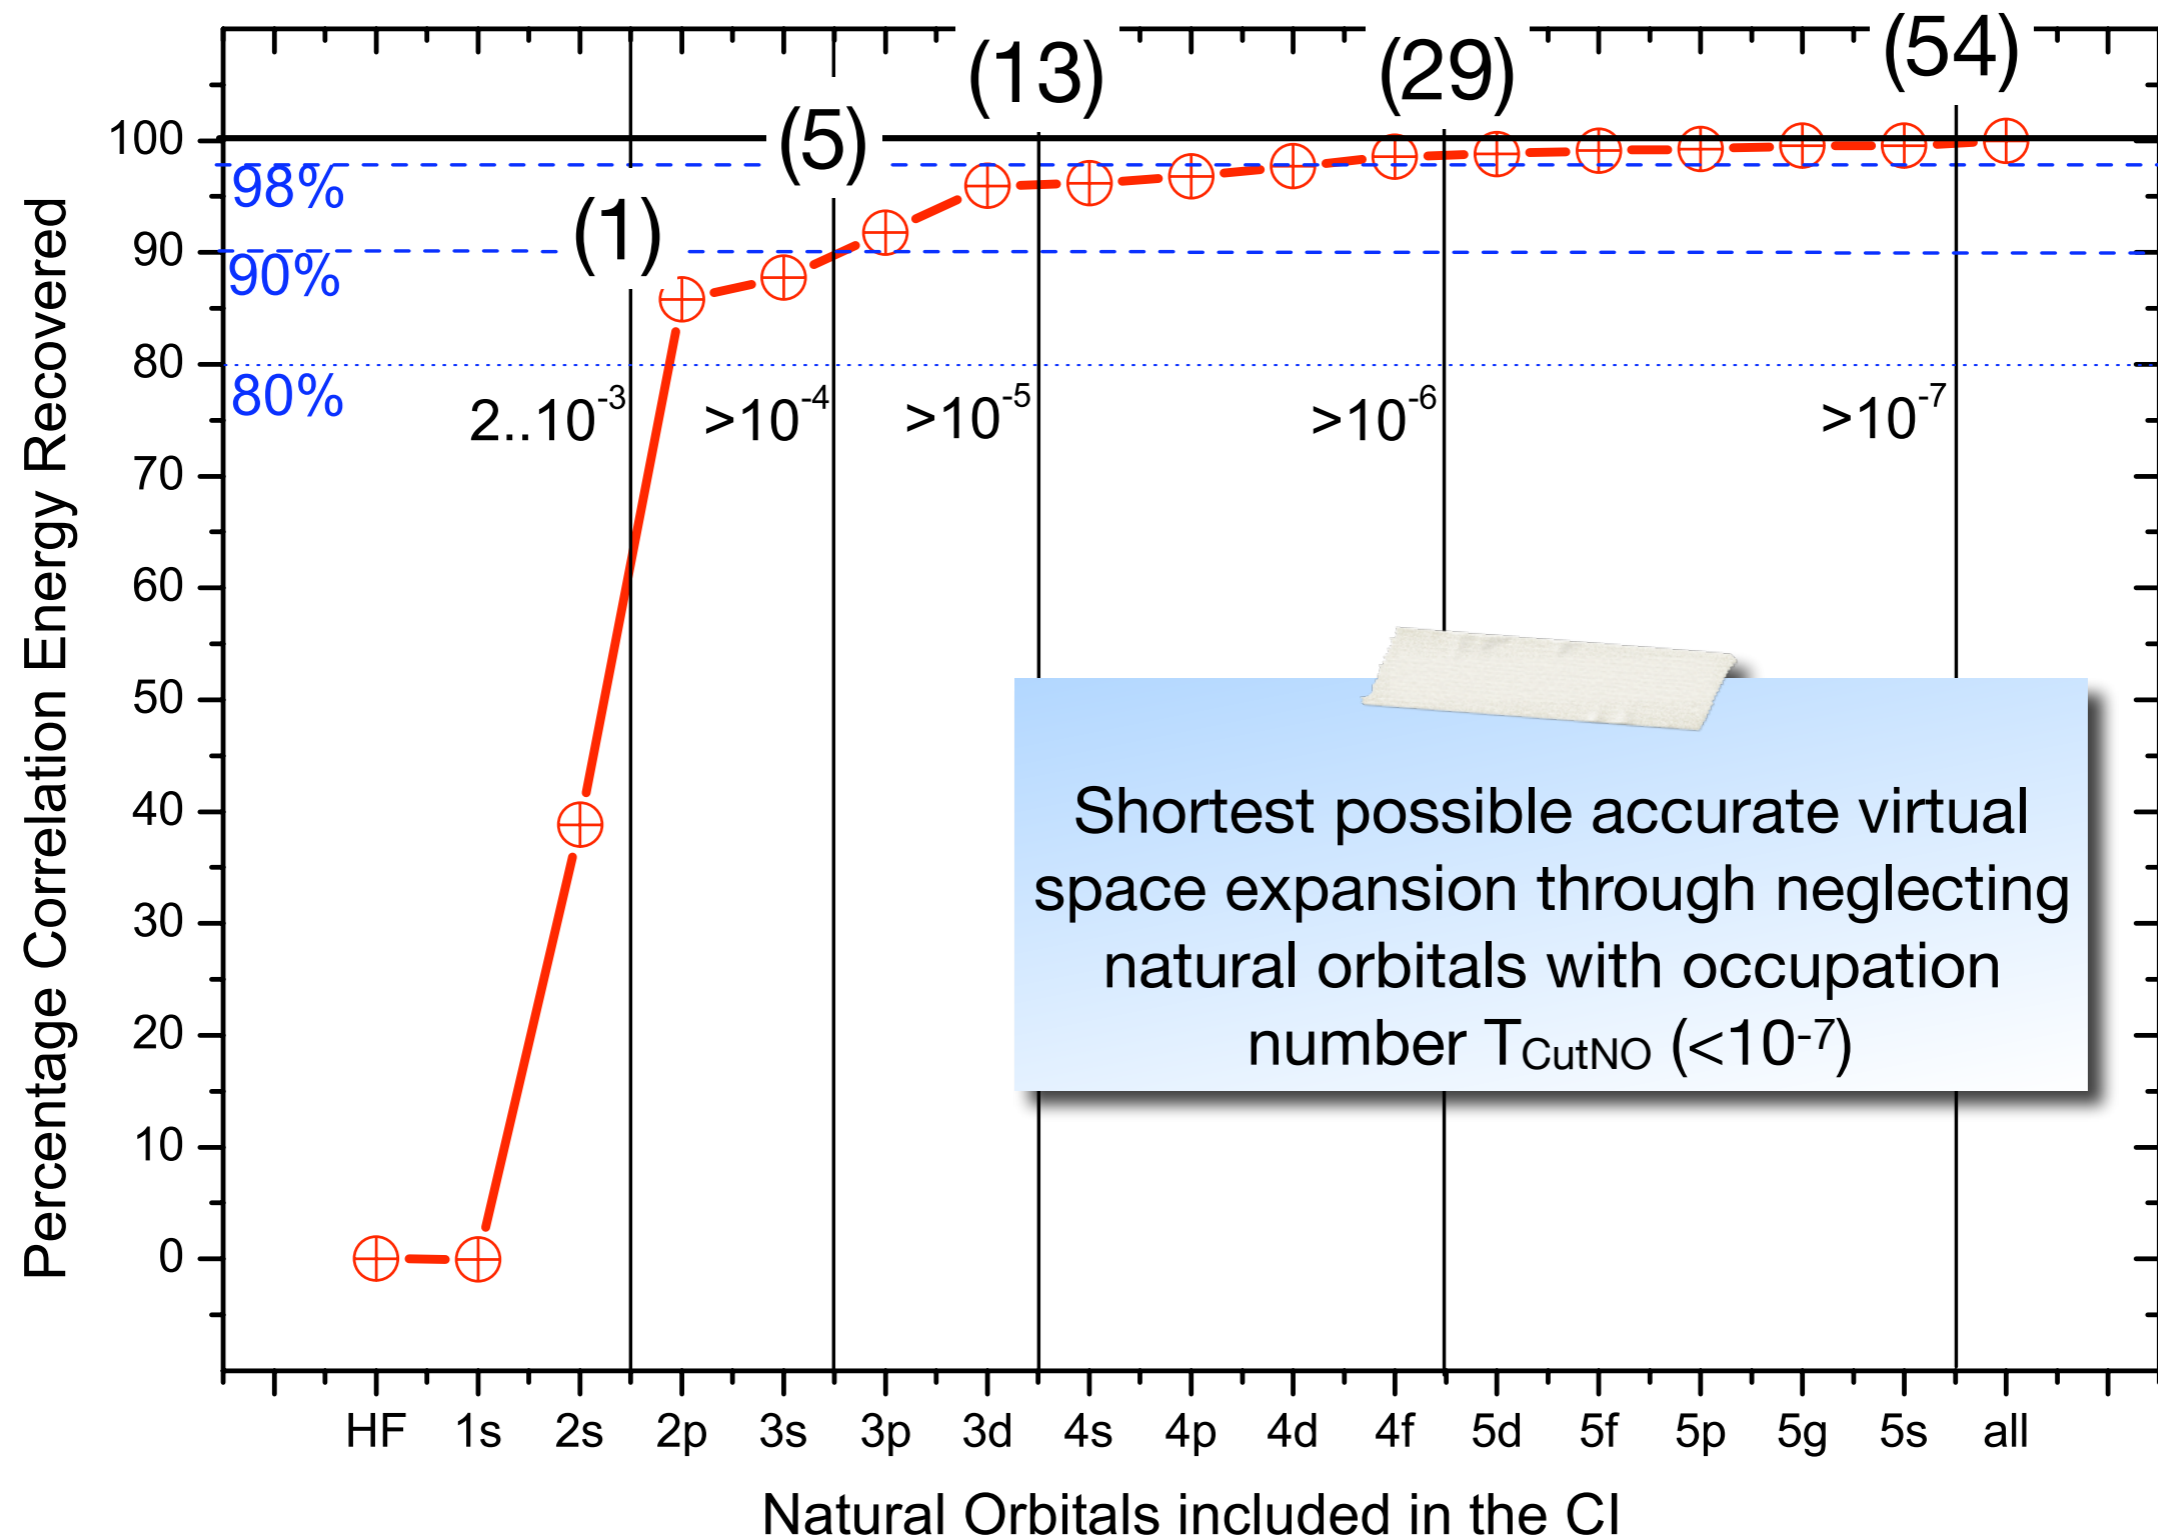

$$\sum_k \gamma_k^2 = \sum_k n_k^2 - \sum_{l \neq k} |\gamma_{kl}|^2 \leq \sum_k n_k^2,$$

with the final result

$$1 - (1/N) \sum_k n_k^2 \leq 1 - (1/N) \sum_k \gamma_k^2,$$

which proves our theorem. This means that the natural spin-orbitals are distinguished not only by having vanishing bond orders but also by giving the smallest number of essential charge orders possible. By investigating the quantity ϑ , one can therefore easily estimate how much improvement one can expect in the convergence of a given configurational interaction series by introducing the natural spin-orbitals.

The Natural Expansion of He

Pseudonatural Orbitals as a Basis for the Superposition of Configurations. I. He_2^+

C. EDMISTON*

(Received 1 December 1965)

The use of pseudonatural orbitals (PNO) is proposed to improve the rate of convergence in the superposition of configurations (SOC). Natural orbitals are determined for selected electron pairs in the Hartree-Fock field of the $n-2$ electron core and are then used as the basis for the total SOC calculation. Since these natural orbitals are not natural for the n -electron system they are considered false or pseudonatural orbitals when used in the n -electron problem.

The PNO basis has been applied to He_2^+ and H_2 to test the convergence. Complete results are reported here only for He_2^+ . The PNO's are quite successful in speeding up the convergence of the SOC and rendering the calculation of correlation energy quite practical in general. Gaussian-type orbitals (GTO) are used throughout and were not a serious impediment to obtaining quantitative accuracy. In fact the large number of unoccupied Hartree-Fock orbitals consequent upon the use of a GTO basis permit a straightforward determination of the PNO orbitals.

Pair Natural Orbitals and the Virtual Space

✓ Exact density $\mathbf{D}_{ab} = \sum_{P \equiv ij} \mathbf{D}_{ab}^{(P)}$ a,b= canonical virtual orbitals
 $P \equiv (ij)$ Pair label

✓ Diagonalize each pair density individually

$$\mathbf{D}^{(P)} \mathbf{d}^{(P)} = \mathbf{n}^{(P)} \mathbf{d}^{(P)}$$

✓ PNO expansion $|\tilde{\mathbf{a}}_P\rangle = \sum_a d_{a\tilde{\mathbf{a}}_P}^{(P)} |a\rangle$ (exact without truncation)

- ▶ PNOs are orthogonal to all occupied orbitals
- ▶ PNOs of a given pair are orthonormal
- ▶ PNOs of different pairs are not orthogonal

$$\langle \tilde{\mathbf{a}}_P | \tilde{\mathbf{b}}_Q \rangle \equiv S_{\tilde{\mathbf{a}}_P, \tilde{\mathbf{b}}_Q}^{(P,Q)} = \sum_{ab} d_{a\tilde{\mathbf{a}}_P}^P d_{b\tilde{\mathbf{b}}_Q}^Q \underbrace{\langle a | b \rangle}_{\delta_{ab}} = (\mathbf{d}^P)^T \mathbf{d}^Q$$

- ▶ PNOs based on local occupied δ_{ab} orbitals are also local

Pair Natural Orbitals and the Virtual Space

✓ Truncation according to $n_a^P < T_{\text{CutPNO}}$

- ▶ Asymptotically constant number of PNOs per pair
- ▶ Minimal error for a given expansion length

✓ Estimate of PNO error: $\Delta E_{\text{PNO}} = \sum_P \varepsilon_P^{(\text{full})} - \varepsilon_P^{(\text{selected})}$

✓ After truncation, try to expand the PNOs of one pair in terms of another pair PNOs:

$$|a_P\rangle \approx \sum_{b_Q} c_{b_Q a_P} |b_Q\rangle$$

$$c_{b_Q a_P} = \langle b_Q | a_P \rangle = S_{b_Q, a_P}^{(Q,P)}$$

- ▶ Expansion is approximate for truncated PNO expansions! (it can be **very** bad)
- ▶ The overlap is a **projector**

Pair Natural Orbitals (PNOs)

- ▶ Small number of significant PNOs per electron pair
- ▶ Vanishing (0-5) PNOs for weak pairs
- ▶ Located in the same region of space as the internal pair but as delocalized as necessary
- ▶ Orthonormal within one pair, non-orthogonal between pairs

Obstacles

- ✓ At threshold 0, each pair dimension = full VMO ▶ Nightmare!
 - ✓ Need to know the exact density to get PNOs ▶ Absurd!
 - ✓ Many more PNOs than VMOs ▶ Integral generation is frightening
- ➔ PNO method that expand PNOs in virtual MOs are possible (and maybe sometimes desirable! e.g. first generation LPNO methods), but it only becomes efficient and linear scaling with further approximations

Domain Based **L**ocal **P**air **N**atural **O**rbital Methods

- ✓ Logical approximation: Expand the PNOs in terms of local virtual orbitals, e.g. PAO's taken from large pair-specific domains

$$|a_{ij}\rangle = \sum_{\tilde{\mu}_{ij}} d_{\mu_{ij}a_{ij}}^{(ij)} |\tilde{\mu}_{ij}\rangle$$

- ✓ The pair density is approximate and comes from (semi-canonical) local MP2:

$$\mathbf{D}^{(ij)} = \mathbf{T}^{(ij)}\mathbf{T}^{(ij)+} + \mathbf{T}^{(ij)+}\mathbf{T}^{(ij)}$$

$$\mathbf{T}_{\tilde{\mu}_{ij}\tilde{\nu}_{ij}}^{ij} = -\frac{(i\tilde{\mu}_{ij} | j\tilde{\nu}_{ij})}{F_{ii} - F_{jj} - \epsilon_{\tilde{\mu}_{ij}} - \epsilon_{\tilde{\nu}_{ij}}}$$

- ➔ The generated PNOs are rather approximate, but experience shows that only minor improvements are possible by making more elaborate choices; the domain approximation is more problematic.

Local Correlation with PNOs: PNO-MP2

Recall: In Nonorthogonal virtuals (exact equation!):

$$\mathbf{R}^{ij} = \mathbf{K}^{ij} + (\mathbf{F}\mathbf{C}^{ij}\tilde{\mathbf{S}} + \tilde{\mathbf{S}}\mathbf{C}^{ij}\mathbf{F}) - \sum_k (f_{ik}\tilde{\mathbf{S}}\mathbf{C}^{kj}\tilde{\mathbf{S}} + f_{kj}\tilde{\mathbf{S}}\mathbf{C}^{ik}\tilde{\mathbf{S}}) = 0 \quad \tilde{S}_{\tilde{a}\tilde{b}} = \langle \tilde{a} | \tilde{b} \rangle$$

- ▶ Throwing out negligible electron pairs (ij) does not change the equations
- ▶ Introducing pair-specific truncated virtual spaces does change the notation:

$$\mathbf{R}^{ij} = \mathbf{K}^{ij} + (\mathbf{F}^{(ij)}\mathbf{C}^{ij} \underbrace{\tilde{\mathbf{S}}^{(ij,ij)}}_{\substack{1 \text{ in PNOs} \\ N_{ij} \times N_{ij}}} + \underbrace{\tilde{\mathbf{S}}^{(ij,ij)}}_{\substack{1 \text{ in PNOs} \\ N_{ij} \times N_{ij}}} \mathbf{C}^{ij}\mathbf{F}^{(ij)}) - \sum_k (f_{ik} \underbrace{\tilde{\mathbf{S}}^{(ij,jk)}}_{\substack{N_{ij} \times N_{kj} \\ N_{kj} \times N_{ij}}} \mathbf{C}^{kj} \underbrace{\tilde{\mathbf{S}}^{(kj,ij)}}_{\substack{N_{kj} \times N_{ij} \\ N_{ij} \times N_{kj}}} + f_{kj} \underbrace{\tilde{\mathbf{S}}^{(ij,ik)}}_{\substack{N_{ij} \times N_{ik} \\ N_{ik} \times N_{ij}}} \mathbf{C}^{ik} \underbrace{\tilde{\mathbf{S}}^{(ik,ij)}}_{\substack{N_{ik} \times N_{ij} \\ N_{ij} \times N_{ik}}}) = 0$$

$$S_{a,b}^{(P,Q)} = \langle \mathbf{a}_P | \mathbf{b}_Q \rangle$$

Thus there is an emerging „**cooking recipe**“:

- ▶ Whenever two pairs are „connected“ there will be mismatched dimensions on the matrices to be multiplied: insert the pair-pair overlap in these terms.
- ▶ In reality it is not quite that simple ...

Steps in DLPNO-MP2

- ✓ Perform **HF** calculation
- ✓ **Localize** occupied MOs – separately for core and valence
- ✓ Construct normalized redundant **PAOs**
- ✓ Select PAO **domains** based on DOI (T_{CutDO})
- ✓ **Screen** *ij*-pairs based on a dipole approximation of the pair energy
- ✓ For every pair domain, construct **quasi-canonical non-redundant PAOs**
- ✓ Calculate the **semi-canonical amplitudes**
- ✓ **Diagonalize** the pair density
- ✓ **Keep PNOs** with occupation $> T_{\text{CutPNO}}$
- ✓ **Solve** MP2 residual equations in PNO basis

DLPNO-MP2: Efficiency and Scaling

ALWAYS faster than even accelerated Hartree-Fock

Early crossover with the canonical RI-MP2 method!

*Domain Based Local Pair Natural Orbital Coupled
Cluster Theory*

The DLPNO-CCSD Approach

The DLPNO approach to CCSD follows as a natural extension to MP2 (although historically, DLPNO-CCSD was much earlier than DLPNO-MP2)

The **cluster operator** is written in the PNO basis:

$$T_1 + T_2 = \sum_{ia} t_{\tilde{a}_i}^i a_{\tilde{a}_i}^+ a_i + \frac{1}{4} \sum_{ijab} t_{\tilde{a}_{ij}\tilde{b}_{ij}}^{ij} a_{\tilde{b}_{ij}}^+ a_{\tilde{a}_{ij}}^+ a_j a_i$$

- ▶ PNO's for doubles are made from DLPNO-MP2 and cut with T_{cutPNO}
- ▶ PNO's for singles are identical to the PNOs of the diagonal pairs and cut with $0.01T_{\text{cutPNO}}$

The **PNOs** are expanded in large PAO domains (using T_{cutDO} for domain construction and T_{cutMKN} for aux-domain construction)

$$|\tilde{a}_{ij}\rangle = \sum_{\tilde{\mu} \in \{ij\}} d_{\tilde{\mu}\tilde{a}}^{ij} |\tilde{\mu}\rangle$$

Natural Triple Excitations

Our suggestion: **Natural triples orbitals** (TNO's)

✓ Three-pair density: $\mathbf{D}^{ijk} = \frac{1}{3}(\mathbf{D}^{ij} + \mathbf{D}^{ik} + \mathbf{D}^{jk})$

(The operator $\hat{D}^{ijk} = \sum_{\bar{a}_{ij}} |\bar{a}_{ij}\rangle\langle\bar{a}_{ij}| + \sum_{\bar{a}_{ik}} |\bar{a}_{ik}\rangle\langle\bar{a}_{ik}| + \sum_{\bar{a}_{jk}} |\bar{a}_{jk}\rangle\langle\bar{a}_{jk}|$ projects onto the joint PNO space of the three pairs)

✓ Formation of the three pair density in the **PAO basis** is linear scaling:

✓ Eigenfunctions: $\mathbf{D}^{ijk} \mathbf{x}^{ijk} = n^{ijk} \mathbf{x}^{ijk}$ (cut-off below a given $n^{ijk}(\text{min})$ just as for PNOs)

✓ Recanonicalize: $\mathbf{x}^{ijk+\mathbf{F}} \mathbf{x}^{ijk}$

✓ Amplitudes are projected into the TNO basis: $T_{\tilde{a}_{ijk}, \tilde{b}_{ijk}}^{ij;TNO} = S_{\tilde{a}_{ijk}, \tilde{c}_{ij}}^{ijk,ij} T_{\tilde{c}_{ij}, \tilde{d}_{ij}}^{ij;PNO} S_{\tilde{b}_{ijk}, \tilde{d}_{ij}}^{ijk,ij}$

➔ Integrals over TNOs must be generated for each triple
(bookkeeping complicated but linear scaling) *avoiding projection*

➔ *Linear scaling implementation achieved (Dr. Christoph Riplinger)*

Convergence of DLPNO-CCSD(T)

- ✓ Typically 99.8-99.9% of the canonical correlation energy
- ✓ Energetics of the canonical counterpart methods is reproduced to a few tenths of kcal/mol. Maximum achievable accuracy ~ 0.1 kcal/mol of the canonical result.
- ✓ The methods are robust and completely black box in character

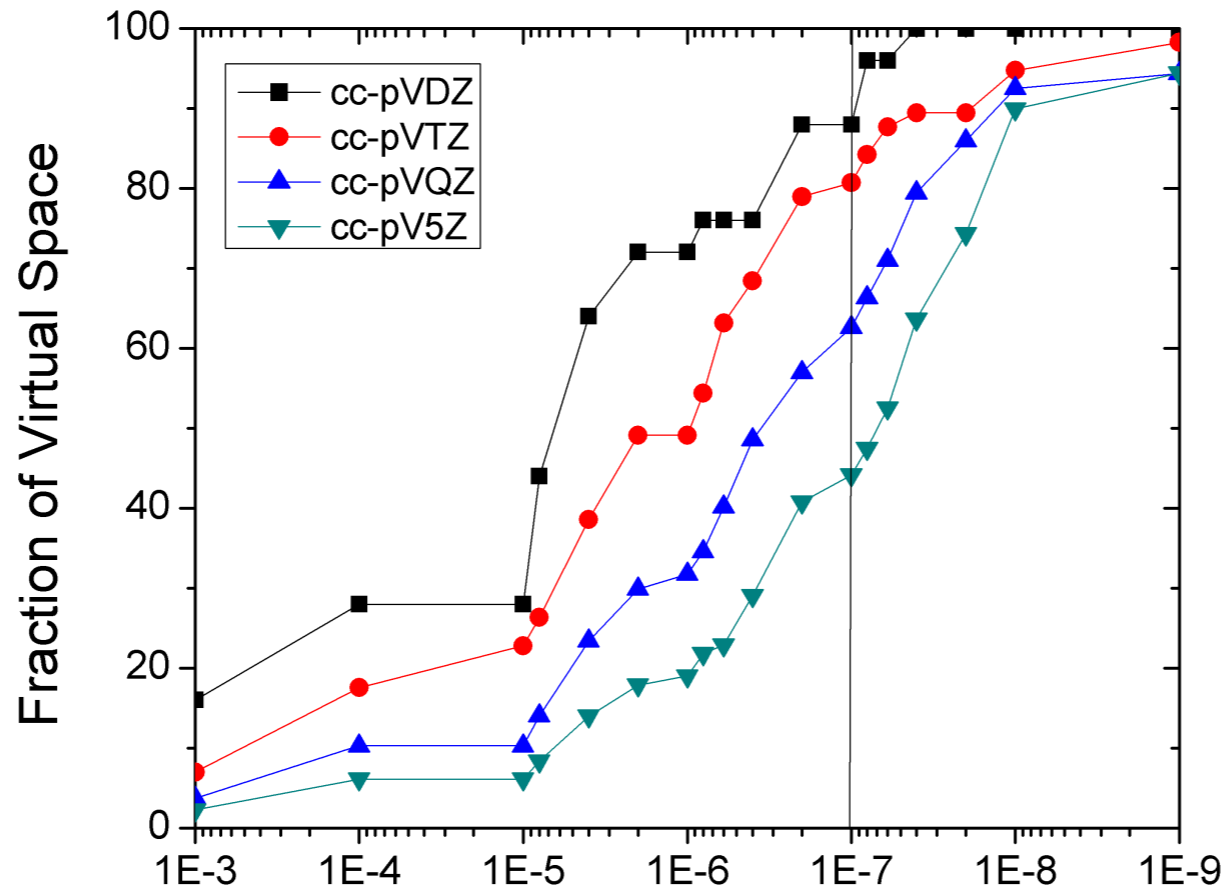

Li-Dimer @ 1.5 Angström

At fixed threshold one recovers less E_c as the basis set is approaching completeness ... $T_{\text{CutNO}}=10^{-7}$ is fine even for large bases

At fixed threshold the number of NOs *is* approaching a constant as the the basis set saturates

At fixed threshold the fraction of the virtual space treated gets smaller as the basis set saturates (cost reduction \sim (fraction)⁴)

Real Life Basis Set Behavior of DLPNO-CCSD(T)

In real life convergence of the PNO expansion is *more* favorable than for, say He, since weakly interacting electron pairs saturate more quickly with basis set!

Efficient DLPNO–CCSD(T)-Based Estimation of Formation Enthalpies for C-, H-, O-, and N-Containing Closed-Shell Compounds Validated Against Critically Evaluated Experimental Data

Eugene Paulechka*^{id} and Andrei Kazakov*

Thermodynamics Research Center, Applied Chemicals and Materials Division, National Institute of Standards and Technology, 325 Broadway, Boulder, Colorado 80305-3337, United States

ABSTRACT: An accurate and cost-efficient methodology for the estimation of the enthalpies of formation for closed-shell compounds composed of C, H, O, and N atoms is presented and validated against critically evaluated experimental data. The computational efficiency is achieved through the use of the resolution-of-identity (RI) and domain-based local pair-natural orbital coupled cluster (DLPNO–CCSD(T)) approximations, which results in a drastic reduction in both the computational cost and the number of necessary steps for a composite quantum chemical method. The expanded uncertainty for the proposed methodology evaluated using a data set of 45 thoroughly vetted experimental values for molecules containing up to 12 heavy atoms is about $3 \text{ kJ}\cdot\text{mol}^{-1}$, competitive with those of typical calorimetric measurements. For the compounds within the stated scope, the methodology is shown to be superior to a representative, more general, and widely used composite quantum chemical method, G4.

Cost vs Accuracy

PNO based coupled cluster methods: Summary

- (1) **(relative) Simplicity.** Only one critical cut-off (T_{CutPNO}); local approximations only ,boost‘ efficiency. T_{CutPNO} can be use to control the absolute desired accuracy
- (2) **No real-space cut-offs** and **no fragmentation** necessary
- (3) **No redundant integral generation** or amplitude optimizations
- (4) **No *reliance* on sparsity** (e.g. not linear scaling ,by construction‘)
- (5) Optimal correlation spaces: a) small for weak pairs, b) as delocalized as necessary
- (6) **Excellent behavior with basis set size**
- (7) Only local method with **proven accuracy** (better than 1 kcal/mol) and **proven efficiency** (approaching SCF/DFT times) for real life applications.
- (8) **Very weak or no dependence on the localization method.** Well localized internal space not even required
- (9) **Very smooth error**; no kinks and jumps in PESs
- (10) **Black box character**
- (11) Meanwhile developed for open shells, excited states, properties, F12, multireference, (gradients),...

Does Local Correlation Solve all Problems?

NO

1. Local correlation- by design - will fail in almost exactly the same way as canonical CCSD(T) does. Hence, it is accurate in the **regime of applicability of CC theory**, not beyond. However, **multi-reference local methods are as successful**.
2. There is a **residual error** that is **size intensive**. It is typically **<1 kcal/mol** (*relative to canonical CCSD(T)*) However, that is **still not zero** (*relative to basis set limit full CI*) and to ,hammer' the total energy down to even higher accuracy is difficult without drastically slowing things down. (Hence, CCSDT and beyond may not be attractive)
3. One ,only' gets an accurate **electronic energy**. For **zero-point, thermal** and **entropy** corrections as well as **solvation** or geometry errors one is stuck with the same errors as before - this is actually now the limiting factor for applications!
